

A How Day 24 and Day 31 TGI are calculated from tumor growth
At each marked endpoint: $TGI = 100 \times (1 - \text{treated growth delta} / \text{mean injected-origin-matched control growth delta})$

Thin lines: individual mice. Dashed black: mean injected-origin-matched untreated controls. Red dashed: Day 24; red solid: Day 31.

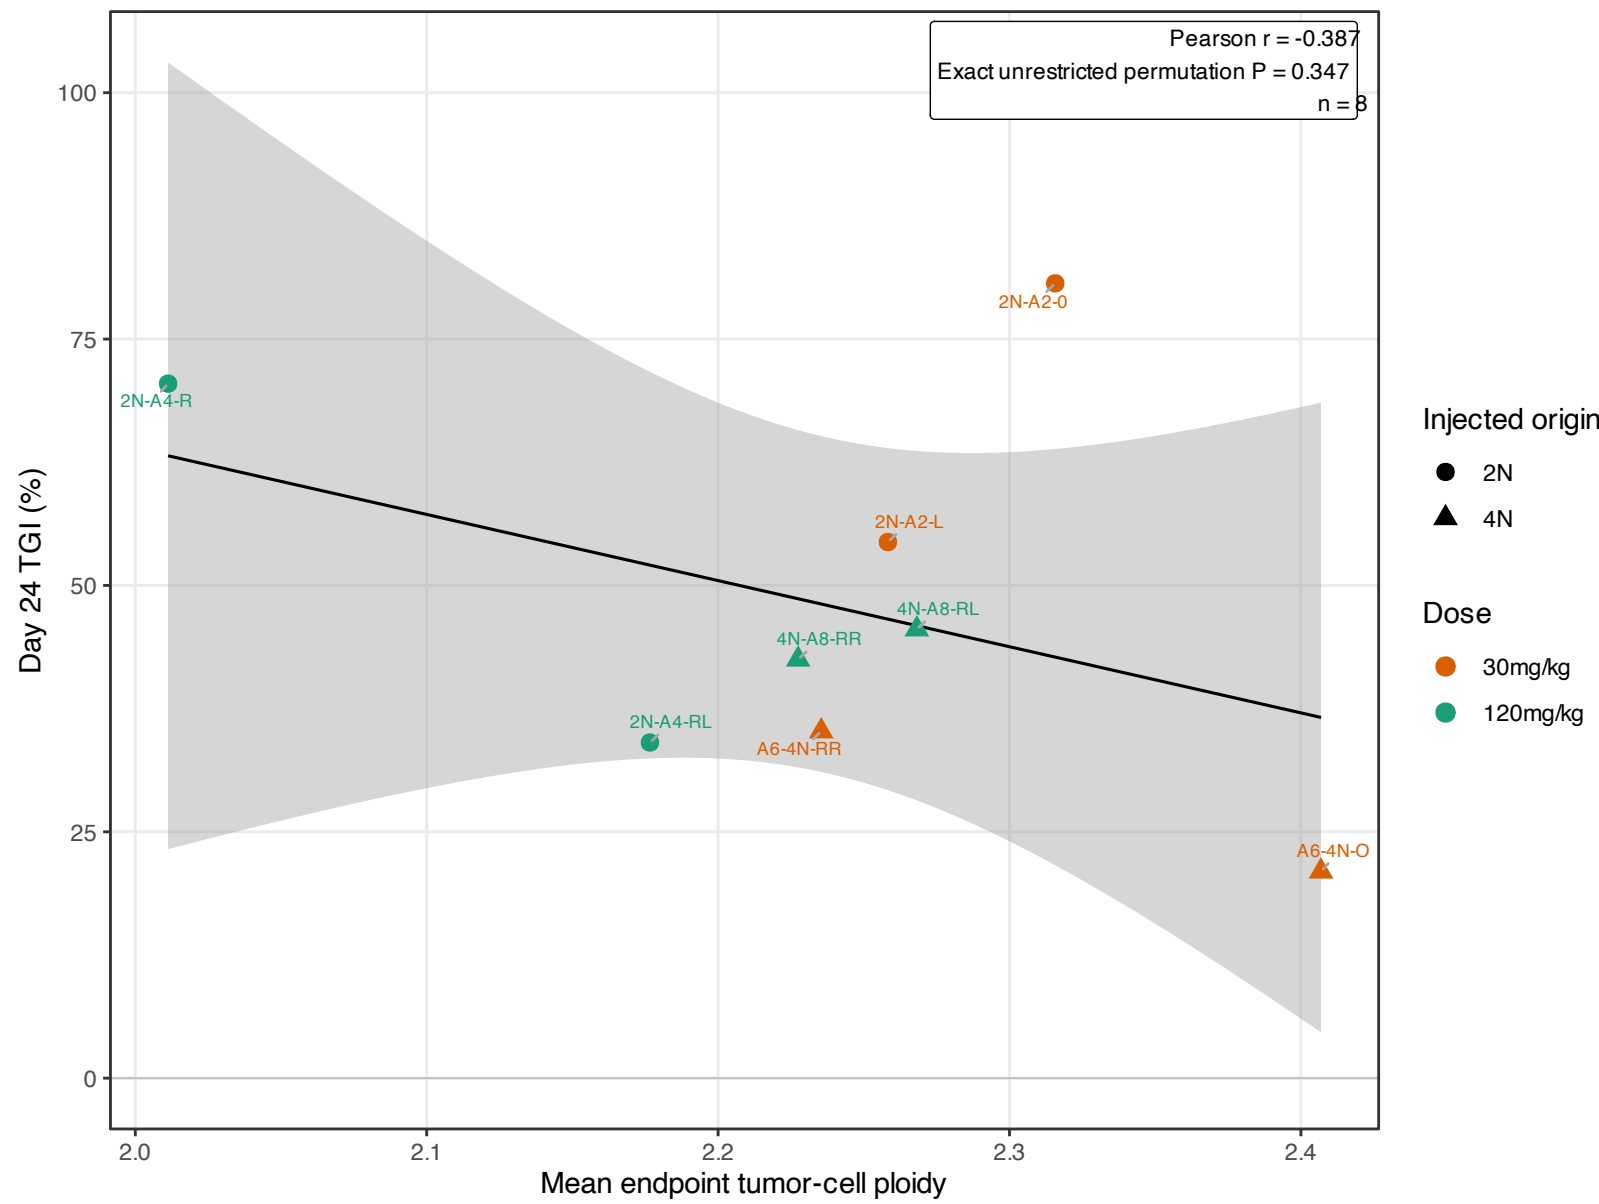

B Treated CellCycle tumors: Day 24 TGI by Initial ploidy

Independent tumors; no one-to-one mouse pairing
Exact dose-stratified permutation
Adjusted delta (4N - 2N) = -23.844 percentage points; P = 0.167
n = 4 (2N) and 4 (4N)

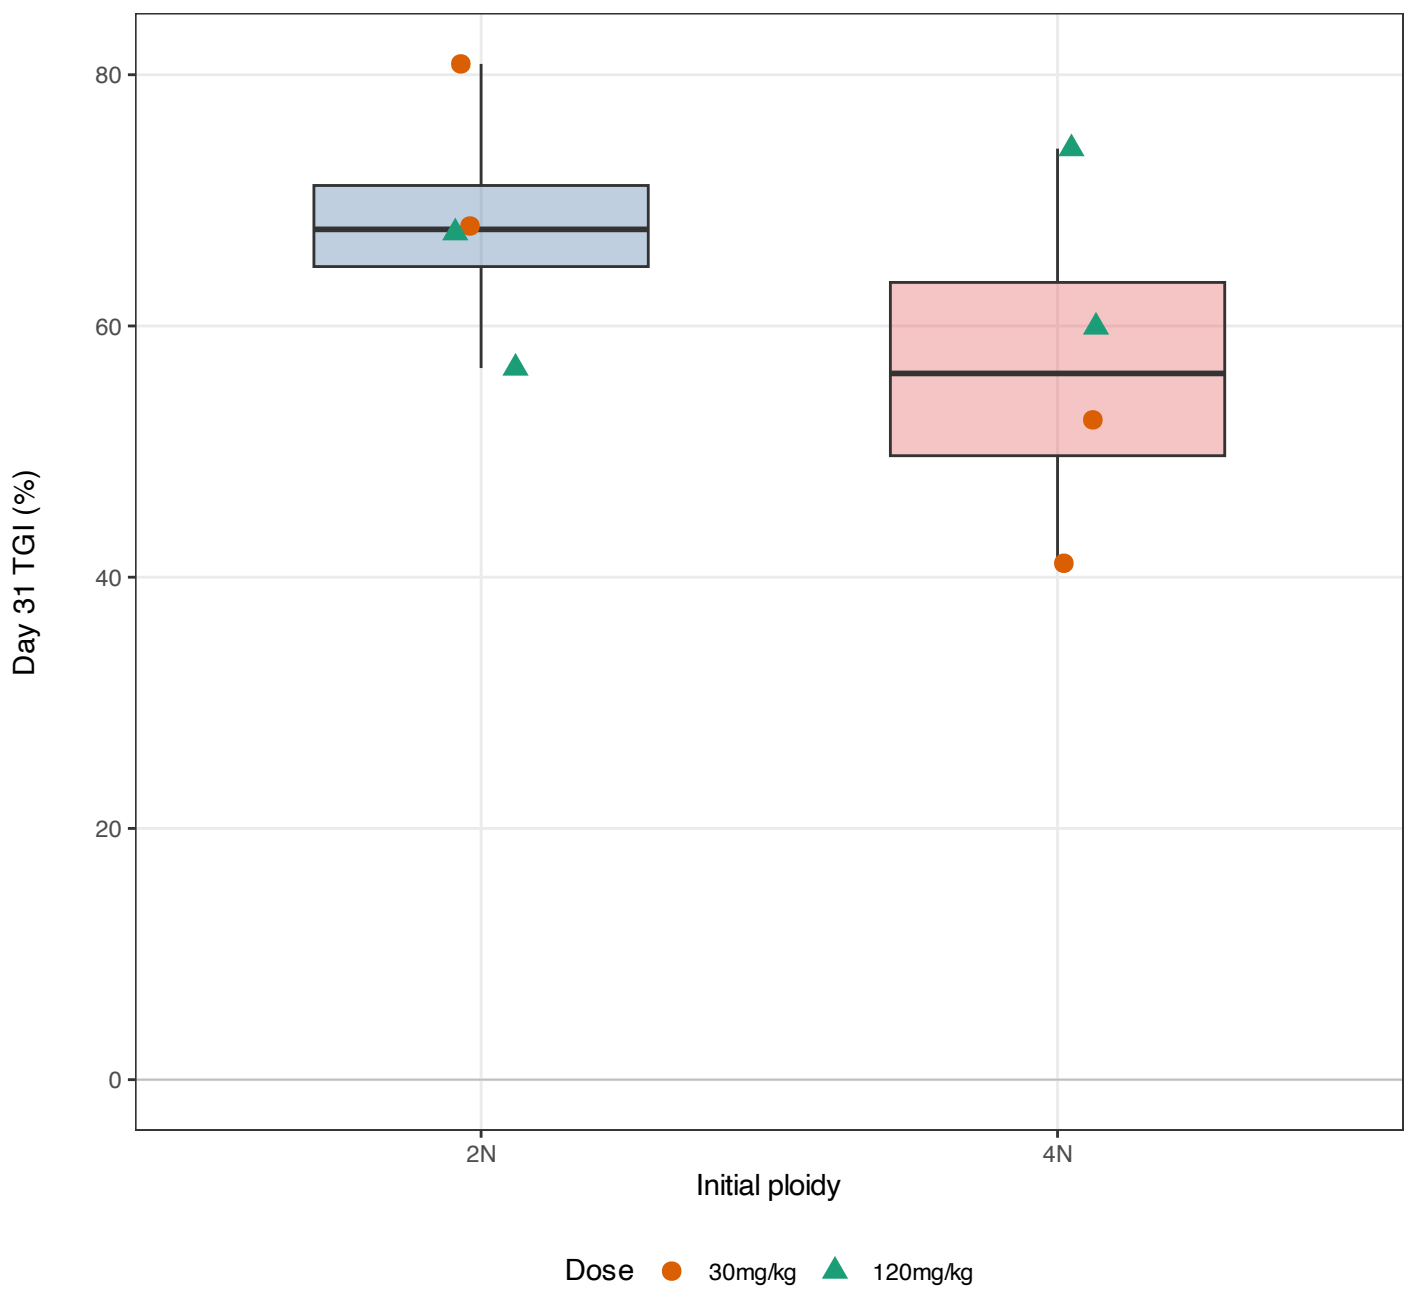

C Day 24 TGI vs mean endpoint tumor-cell ploidy

5,335 QC-passed treated-tumor CBS cells; unadjusted mouse-level association

D Treated CellCycle tumors: Day 31 TGI by Initial ploidy

Independent tumors; no one-to-one mouse pairing
Exact dose-stratified permutation
Adjusted delta (4N - 2N) = -11.306 percentage points; P = 0.306
n = 4 (2N) and 4 (4N)

E Day 31 TGI vs mean endpoint tumor-cell ploidy

5,335 QC-passed treated-tumor CBS cells; unadjusted mouse-level association
